

BUILD FOR BILLIONS – INITIAL SCREENING PROPOSAL

AgenticAIforBillions | TeamWaveTech

Team Name	WaveTech
Team Leader	Maajida farjana
Team Members	Maushami, Medha, Fathimathul Umaina, Disha Shanbhag , Anwitha .
College/University	Canara engineering college
Selected Track	Agentic AI for Billions
Project Title	SevaSathi AI – Multilingual Public-Service Action Assistant

1. Problem Statement

Many citizens, students, senior citizens, and people with limited digital literacy find it difficult to understand and access public-service information. Information is often spread across multiple websites, written in formal language, or available only in languages that users may not understand comfortably. Users may not know which service they need, what documents are required, what steps to follow, or where to find the official application link. This creates confusion, repeated visits, dependence on intermediaries, and the risk of relying on incorrect information.

Core problem: Users need a simple, multilingual and trustworthy assistant that can understand their request, identify the relevant public service, explain the process, and guide them to the appropriate official source.

2. Proposed Solution

SevaSathi AI is a multilingual, agentic AI assistant that helps users discover and understand public services through a conversational interface. Instead of only generating a generic answer, the assistant follows a controlled workflow: it identifies the user's intent, searches a verified service knowledge base, retrieves relevant information, prepares a step-by-step response, and provides official links for further action.

Planned key features:

- Multilingual text-based interaction, beginning with English and one Indian language selected by the team.
- Service discovery based on the user's natural-language request.
- Step-by-step guidance covering eligibility, required documents, process and official links.
- Source-grounded responses using a curated database of verified public-service information.
- Clarification questions when the user's request is incomplete or ambiguous.
- Fallback response when reliable information is unavailable; the assistant will not invent official rules or claim to submit an application.

How the agent works

1	Understand	Identify the user's language, intent and requested service.
2	Clarify	Ask a short follow-up question if important information is missing.
3	Retrieve	Search the approved service information database.
4	Respond	Generate a clear, structured explanation with source references.
5	Guide	Show the official link and next steps for the user.

3. Target Users & Impact

The primary target users are people who face difficulty navigating digital public-service information, including students, first-time applicants, senior citizens, users with limited digital literacy, and people who prefer regional languages.

Expected impact:

- Reduce the time and confusion involved in finding public-service information.
- Improve access for users who are more comfortable using a regional language.
- Present complex procedures in a simple, step-by-step format.
- Reduce dependence on unofficial intermediaries by linking users to official sources.
- Create a reusable framework that can be extended to additional services, languages and user groups.

4. Technology Stack

Layer	Proposed Technology / Use
Frontend	React or HTML, CSS and JavaScript for a responsive web interface.
Backend	Python with FastAPI or Node.js for API endpoints and application logic.
AI layer	LLM API for intent understanding, clarification and response generation.
Knowledge base	Structured JSON/CSV data or Supabase/Firebase containing curated service information.
Retrieval	Keyword search or basic retrieval pipeline; upgradeable to embeddings/vector search.
Deployment	Vercel/Netlify for frontend and Render/Railway or a similar platform for backend, subject to availability.
Version control	Git and GitHub for collaboration and version tracking.

5. Innovation & Scalability

The proposed solution combines a conversational AI interface with a controlled, source-grounded workflow for public-service guidance. The focus is not only on generating text, but on helping the user move from an unclear request to a structured set of next steps.

- Agent workflow: intent detection, clarification, retrieval and guided response generation.
- Trust-oriented design: responses are based on a curated knowledge base and include official references wherever possible.
- Multilingual accessibility: the interface and response layer can be extended to additional Indian languages.
- Modular architecture: new services can be added by updating the service database rather than rewriting the entire application.
- Scalability: the system can later support voice input, accessibility features, additional public-service categories and integrations with approved APIs.

6. Prototype / References

At the time of proposal submission, the team plans to develop the prototype during the hackathon. A working prototype, wireframe or GitHub repository will be added if available before submission.

Planned initial prototype screens: Home / language selection, service search, service details, AI assistant chat, and official-link guidance page.

References to be collected by the team: official public-service portals and government information pages relevant to the selected demo services. The team will verify the accuracy and date of the information used in the prototype.

7. Team Contribution

Member	Expected Contribution
--------	-----------------------

Fathimathul Umaina	Frontend development: page layouts, navigation and responsive user interface.
Medha	Backend development: APIs, request handling and integration.
Maushami	AI integration: prompts, agent workflow and response testing.
Disha Shanbhag	Research and knowledge base: collect, structure and verify service information.
Anwitha	UI/UX and quality testing: user flow, accessibility and bug testing.
Maajida farjana	Integration and presentation: GitHub coordination, deployment, documentation and final demo.
